

Structural bearings

LASTO[®]BLOCK elastomeric bearings

Selection of bearings

mageba LASTO[®]BLOCK elastomeric bearings accommodate the following demands:

- Vertical loads
- Transient external horizontal forces
- Horizontal movements in all directions (by shear deformation)
- Rotation about all axes

In order to determine bearing dimensions, the following parameters must be known:

- Vertical loads: N_{dmax} and N_{dmin}
- Displacements: v_{xyd}
- Rotations: α_{ab}
- Bearing shape (round or rectangular) and maximum dimensions (if space is limited)
- Contact surfaces (steel or concrete)

Basis of design

According to EN1337, the following verifications must be performed for elastomeric bearings:

- Maximum strain (strain resulting from vertical loading, shear strain from horizontal displacement, and strain from rotation)
- Thickness of internal and external reinforcing plates
- Limiting condition for rotation
- Stability in terms of sliding

The load bearing capacity of a bearing depends on several factors. The suitability of a bearing must be verified on a case by case basis, with consideration of all relevant factors.

Principles of load table use

A bearing of any size can be subjected to various load / deformation conditions; as vertical load on the bearing increases, the allowable horizontal deformation (displacement) decreases. Each bearing size is capable of allowing a certain maximum horizontal deformation, $V_{xy,max}$ which is only allowed when the vertical load is sufficiently low. If a lower horizontal deformation arises ($V_{xyd} < V_{xy,max}$), then the permissible vertical load increases. To standardise bearing production and selection, the following three conditions are defined:

- Condition 1: $V_{xyd} = 20\%$ of $V_{xy,max}$
- Condition 2: $V_{xyd} = 50\%$ of $V_{xy,max}$
- Condition 3: $V_{xyd} = 100\%$ of $V_{xy,max}$

Each bearing size can support varying vertical loads, depending on which condition is considered. Therefore, a bearing size should be selected for each of the three conditions, to enable the most economical to be selected.

Support

Our product specialists are always ready to advise you in selecting the optimal solution for your project, and to provide you with quotations for supply.

You can also find further information at mageba-group.com and in the relevant product brochure.

1 Bearing dimensions determined based on Condition 1

2 Bearing dimensions determined based on Condition 2

3 Bearing dimensions determined based on Condition 3

Instructions for using the tables

Selection of the required bearing dimensions is performed in three steps (using typical loading conditions), with the aid of the following tables (see pages). A suitable bearing size, which satisfies the specified design requirements (N_d , N_{dmin} , v_{xyd} , α_{ab}), should be chosen for each load condition.

The bearing dimensions should preferably be initially selected based on the movement capacity to be accommodated. Vertical loads and rotations should then be checked (see example).

After the three bearing sizes have been determined, the smallest can generally be selected as the most economical.

<p>Example:</p> <ul style="list-style-type: none"> Bearing type: B Connecting material: concrete at both sides Loads: $N_d = 114$ kN N_{dmin} (actual) = 74 kN Displacement: $v_{xy} = 13.5$ mm Rotation: $\alpha_{ab} = 1.0$ % 	<p>1. Determination of bearing dimensions based on Condition 1: $v_{xyd} = 20\% \times v_{xy,max}$</p> <p>→ Bearing dimensions: 300 × 400 × 105 mm $(v_{xyd} = 15.4 \text{ mm} > 13.5 \text{ mm}, N_d = 1720 \text{ kN} > 114 \text{ kN}, \alpha_{ab} = 3.0\% > 1.0\%)$ Note: N_{dmin} (required to prevent sliding) = 326 kN > N_{dmin} (actual)</p> <p>(Because the min. load required to prevent shifting by friction is not available, this bearing size must be prevented from becoming displaced by other measures, e.g. upstands at each corner. An alternative is to use an elastomeric bearing of Type C with shear lugs or bolts)</p> <p>2. Determination of bearing dimensions based on Condition 2: $v_{xyd} = 50\% \times v_{xy,max}$</p> <p>→ Bearing dimensions: 150 × 200 × 41 mm $(v_{xyd} = 14.5 \text{ mm} > 13.5 \text{ mm}, N_d = 366 \text{ kN} > 114 \text{ kN}, \alpha_{ab} = 1.6\% > 1.0\%)$ Note: N_{dmin} (required to prevent sliding) = 74 kN = N_{dmin} (actual)</p> <p>3. Determination of bearing dimensions based on Condition 3: $v_{xyd} = 100\% \times v_{xy,max}$</p> <p>→ Bearing dimensions: 100 × 200 × 30 mm $(v_{xyd} = 21.0 \text{ mm} > 13.5 \text{ mm}, N_d = 139 \text{ kN} > 114 \text{ kN}, \alpha_{ab} = 1.3\% > 1.0\%)$ Note: N_{dmin} (required to prevent sliding) = 45 kN < N_{dmin} (actual)</p> <p>→ Result: A bearing with the dimensions 100 × 200 × 30 mm represents the most economical solution.</p>
--	---

Note: Please note that the following tables should only be used to determine approximate bearing dimensions. More precise dimensions / optimised sizes can be advised by mageba on request.

Variables

a : bearing width (shorter side in case of a rectangular bearing)	N_d : vertical load bearing capacity (design level)
b : bearing length (longer side in case of a rectangular bearing)	N_{dmin} (concrete) : required min. vertical load with concrete connection (design level)
t : bearing height	N_{dmin} (steel) : required min. vertical load with steel connection (design level)
T_e : nominal thickness of all elastomer layers	v_{xyd} : resultant horizontal displacement
K_z : vertical stiffness of bearing	$v_{xyd,max}$: maximum resultant horizontal displacement
K_{xy} : horizontal stiffness of bearing	α_{ab} : resultant rotation
